How to round up? I'm rounding a float to 32 bits when converting to a float: from fractions import Fraction from math import * def floor(x, base): return int(x+0.5*Fraction(x)) However, if I try to round up an exact value of 5.125147476336180E-16 I get 5.125147476336181E-16 instead: >>> round(5.125147476336180E-16) 5.125147476336180E-16 Is there a way to round up? A: In general, you should use round(x, up=False) for this. A: It sounds like you want: >>> import math >>> math.floor(5.125147476336180E-16) 5.125147476336180E-16 Since: >>> math.floor(5.125147476336180E-16) == float(5.125147476336180E-16) True >>> math.floor(5.125147476336180E-16) == round(5.125147476336180E-16) True Q: How do I print a message to the terminal using the printf function in libc? Can I programmatically print a message to the terminal using the printf function in libc? I mean without using os.write(1, message), just printf(message), or something else? A: You can specify the writing to the terminal if you use functions such as perror. For example, int err = perror("I'm a bug!"); fprintf(stderr, "I threw a %s ", err); These calls return 0 if they succeed and another number if they fail. A: int fprintf(FILE *stream, const
